

A named carriers retain different information

B information ledger on the regular torsor

carrier	order r_q	orbit type	labelled twist	isotropy	native period
point Burnside	yes	[G/1]	subgroup only	marks	r_q
point orbifold	yes	scalar	no	weight	r_q
orbit Burnside	no	[G/1]	no	marks	1
$\mathbb{Z} \times G$ perm.	yes	yes	a_q^{-1}	yes	labelled
enhanced carrier	yes	yes	a_q	character	labelled
stack / inertia	no	B1	no	identity	1

The rows are distinct established constructions; this is not a universal dominance order.

C scalar support/exponent ledger

reduction	support / exponent	scope
$\kappa(\text{point})$	support a_q exponent m_q	unit when $m_q \approx 1$
$\Phi(\text{point})$	$(r_q, 1/r_q)$	fractional
$\kappa(\text{orbit})$	$(1, n_q)$	static support
$\Phi(\text{orbit})$	$(1, 1)$	static unit
$q \in 2 \times \kappa(\text{point}) = (2, 1) \times$ some locked row type exception. $r_q = r_q = 3$, support 3 does not identify q .		

Family-level conclusion: no one scalar-reduction type combines source support and unit exponent uniformly over all nine locked rows.
