

An Exact Affine Perpetuity and Palm Occupation Certificate for Linear-Rate AIMD

HCS Research Program

30 August 2026 (revision 2)

Abstract

We study the hybrid process $\dot{X} = a > 0$ with jump intensity ρX and multiplicative decrease $X \mapsto \beta X$, $0 < \beta < 1$. For the pre-jump value Y_n , completing the integrated hazard gives the exact square-affine chain $Y_{n+1}^2 = \beta^2 Y_n^2 + 2aE_{n+1}/\rho$. This yields a unique stationary affine perpetuity, a source-local Laplace q-product, all squared moments, the generator moment recursion, and a stationary Markov-renewal/Palm occupation formula. The receipt covers 27 rational parameter tuples and exact reward skeletons, with independent checking, symbolic identities, replay, and hostile mutations. For positive β the jump sequence is Markov rather than iid regenerative; $\beta = 0$ is the separate reset face. No arithmetic target determinant is claimed, so the strict Route-A verdict is `ROUTE_A_REJECTED`.

1 Process and the pre-jump chain

Between jumps let $X_t = \beta Y_n + at$, where Y_n is the value immediately before the preceding jump. The next waiting time T_{n+1} is determined by the integrated hazard

$$\rho \left(\beta Y_n T_{n+1} + \frac{a T_{n+1}^2}{2} \right) = E_{n+1}, \quad E_{n+1} \sim \text{Exp}(1), \quad (1)$$

and $Y_{n+1} = \beta Y_n + a T_{n+1}$.

Theorem 1 (Square-affine recurrence). *For every $a, \rho > 0$ and $0 < \beta < 1$,*

$$Y_{n+1}^2 = \beta^2 Y_n^2 + \frac{2a}{\rho} E_{n+1}. \quad (2)$$

Proof. Expand $(\beta Y_n + aT)^2 - \beta^2 Y_n^2 = 2a(\beta Y_n T + aT^2/2)$ and use (1). The factor a cannot be dropped. $\square$

Theorem 2 (Perpetuity and uniqueness). *With $Z_n = Y_n^2$, synchronous coupling under common exponentials satisfies $|Z_n - Z'_n| = \beta^{2n} |Z_0 - Z'_0|$. Consequently*

$$Z_\infty = \frac{2a}{\rho} \sum_{j \geq 0} \beta^{2j} E_{-j}$$

converges almost surely and is the unique stationary jump-chain law; every finite initial state converges to it.

Proof. The geometric coefficients have finite sum $\mathbb{E} Z_\infty = (2a/\rho)/(1 - \beta^2) < \infty$, so the nonnegative perpetuity series is finite almost surely. The coupling identity contracts every initial pair, so two stationary versions coincide and the finite-start law converges weakly (indeed in Wasserstein metrics with a finite first moment). $\square$

2 Laplace product and moments

Independence of the exponential innovations gives the source-local transform

$$\psi(s) = \mathbb{E}[e^{-sZ_\infty}] = \prod_{j \geq 0} \left(1 + \frac{2a}{\rho} \beta^{2j} s \right)^{-1}. \quad (3)$$

The release stores a 12-factor rational prefix and three rational spot values for every frozen parameter tuple. Equation (3) is probability bookkeeping, not an arithmetic Euler product or a target determinant.

For the continuous-time stationary law let $\varphi(s) = \mathbb{E}[e^{-sX}]$. Applying the generator (6) to e^{-sx} gives the source-local Laplace-generator identity

$$\varphi'(s) - \varphi'(\beta s) = \frac{a}{\rho} s \varphi(s). \quad (4)$$

It is not a target continuation or functional equation.

Writing $m_k = \mathbb{E}[Z^k]$, expansion of (2) yields

$$(1 - \beta^{2k})m_k = \sum_{j=0}^{k-1} \binom{k}{j} \beta^{2j} \left(\frac{2a}{\rho}\right)^{k-j} (k-j)!m_j, \quad m_0 = 1. \quad (5)$$

All entries in the finite receipt are exact rational numbers.

3 Stationary occupation formula

The continuous-time generator is

$$(Lf)(x) = af'(x) + \rho x [f(\beta x) - f(x)]. \quad (6)$$

For stationary moments $M_m = \mathbb{E}[X^m]$, applying (6) to x^m gives

$$\rho(1 - \beta^m)M_{m+1} = amM_{m-1}, \quad m \geq 1. \quad (7)$$

Thus $M_0 = 1$, $M_1 = \mu$, and all higher moments are exact affine expressions in the single Palm-determined mean μ .

Let π denote the stationary pre-jump law. A cycle from βY_n to Y_{n+1} has duration $T = (Y_{n+1} - \beta Y_n)/a$ and monomial reward

$$\int_0^T (\beta Y_n + at)^m dt = \frac{Y_{n+1}^{m+1} - (\beta Y_n)^{m+1}}{a(m+1)}. \quad (8)$$

The stationary Markov-renewal/Palm ratio is therefore

$$M_m = \frac{1 - \beta^{m+1}}{(m+1)(1 - \beta)} \frac{\mathbb{E}_\pi[Y^{m+1}]}{\mathbb{E}_\pi[Y]}, \quad \mu = \frac{a}{\rho(1 - \beta)\mathbb{E}_\pi[Y]}. \quad (9)$$

For $\beta > 0$, π is a stationary Markov jump-cycle law: (8) is not an iid regeneration assertion.

4 Finite certificate and literature context

The exact receipt evaluates all $3^3 = 27$ tuples $\beta \in \{1/2, 2/3, 3/4\}$, $a \in \{1/2, 1, 3/2\}$, and $\rho \in \{1/2, 1, 2\}$. It records orders 0–8, a 12-factor prefix, and a six-step rational hazard skeleton chosen by $Y_{n+1} - \beta Y_n = 1$. The producer-independent checker passes 75 assertions, SymPy passes 96 identities, byte replay matches two fresh runs, and 36 hostile mutations are rejected.

Dumas, Guillemin, and Robert give a Markovian AIMD analysis and invariant probabilities [1]; Guillemin, Robert, and Zwart analyze AIMD algorithms through exponential functionals [2]. These are publisher/DOI references for context, not arithmetic or target spectral certificates.

5 Boundary faces and Route-A scope

At $\beta = 0$ the post-jump state is zero and successive cycles are iid: this is the genuine reset/regeneration face. Its pre-jump density is $f_Y(y) = (\rho/a)ye^{-\rho y^2/(2a)}$, and its continuous-time occupation density is the half-normal $f_X(x) = \sqrt{2\rho/(\pi a)}e^{-\rho x^2/(2a)}$, with mean $\sqrt{2a/(\pi\rho)}$. At $\beta = 1, a > 0, \rho > 0$ contraction is lost and positive drift has no invariant law. On the closed half-line, $a = 0, 0 \leq \beta < 1, \rho > 0$ has only the invariant atom δ_0 , hence no invariant probability on $X > 0$; $a = 0, \beta = 1, \rho > 0$ leaves every law invariant, as does $a = \rho = 0$. If $\rho = 0, a > 0$, linear escape gives no invariant law. There is no intrinsic prime carrier (A0_FAIL), no target determinant or zero matching (A2_FAIL), and no target continuation or functional equation (A3_FAIL). The strict tuple is

$$(\text{AO_FAIL}, \text{A1_FAIL}, \text{A2_FAIL}, \text{A3_FAIL}, \text{A4_FORMAL_HINT}),$$

with ROUTE_A_REJECTED, NO_BAD_EULER_OR_ROOT_NUMBER, and Route B disabled. The q-product remains source-local probability data.

Declarations

Scope. NO_BAD_EULER_OR_ROOT_NUMBER; no arithmetic, target-zero, Euler-factor, root-data, automorphy, or Hilbert–Pólya claim is made. **Data and code.** Exact receipts, independent checker, replay, and mutation audit are included. **AI-use disclosure.** Generative tools assisted drafting and code generation; formulas and metadata are checked by the deterministic artifact chain.
