Abstract

This report asks what exact-certificate architecture could eventually support primitive-geodesic ownership decisions for a source-locked Bolza surface and one frozen nonarithmetic genus-two control at $\Lambda = 21/10$. Stage 1 executed a closed-corpus literature synthesis, not a census or algorithm validation. The evidence supports object, candidate-generation, conjugacy, root-decision, owner-semantics, rigorous-predicate, and producer-checker components, but identifies no project owner. The review-adjudicated architecture permits two surface-specific exact proof producers, provided they emit one common semantic owner-certificate schema checked by an independent validator. The schema separates full-group conjugacy, maximal-root and primitivity evidence, external inversion pairing, self-reciprocity, repetitions, termination, completeness, and positive or negative replay payloads. It requires no common internal solver or input model. Production implementation remains absent. The target-empty and control-nonempty directions at the frozen cutoff are unverified inherited architecture-only assumptions. If each direction is later replayed with source- and hypothesis-adequate proof records, it may condition the corresponding producer obligation; until then neither direction is a scientific result or a basis for between-surface arithmetic inference. P33-RC-1 remains a producer-soundness, schema-interoperability, and independent-validation contract with a fail-closed not-evaluable endpoint. The contribution is an interoperable certificate-methods design with synthetic conformance support, not a census, novelty claim, magnetic or determinant result, formal Route-A tuple, A0/A1/A2 closure, Route-A credit, or Route-B progress.

Keywords: genus-two surface; Bolza surface; primitive geodesic; conjugacy certificate; inversion-paired owner; evidence synthesis; independent validation

繁體中文摘要

本研究探討：在兩個來源鎖定的緊緻虧格二雙曲曲面上，何種精確憑證架構可支援原始閉測地線的所有權判定。研究對象固定為 Bolza 目標曲面與一個非算術控制曲面，動力學子型固定為單位速率的物理基底測地時間、磁場參數 $b = 1/2$ 及有號磁場的偶數子序列；共同截斷值維持為 $\Lambda = 21/10$ ，且不得依已知方向重新調整。本研究實際執行的是封閉語料的文獻查核、證據整合及方法設計，並未執行測地線普查、共軛判定、原始根判定、數值實驗或路線圖評分。綜合結果支持一項受限架構：兩個曲面可採用各自專屬的精確證明產生器，但輸出必須進入共同的語義憑證綱要，再由獨立驗證器檢查。綱要須分離完整群共軛、最大根與原始性、外部反元素配對、自互反性、重複軌道、終止性、完備性，以及正面或負面的重播證據。共同語義不要求共同的內部演算法或數值表示。目標端空集合與控制端非空集合的方向，均僅是未驗證的繼承架構假設。若日後分別以來源與假設充分的證明記錄成功重播，才可把相應方向作為條件式的產生器輸入；在此之前，兩端差異不得支持空與非空比較、算術性推論、A0/A1/A2 關閉、Route A 計分或 Route B 進展。P33-RC-1 的七項義務仍為零項完成；產生器、綱要、驗證器與普查均未實作。本文的落地成果是可稽核的憑證方法設計，而不是已完成的科學普查、磁流或行列式結果，也不是 Route A 或 Route B 的正式結論。

關鍵詞：虧格二曲面；Bolza 曲面；原始測地線；共軛憑證；反元素配對；證據整合；獨立驗證

1 Introduction

1.1 Problem and scope

A primitive closed-geodesic list is not automatically an ownership theorem. For this project, one unoriented primitive owner is the unit

$$\{[g]_{\Gamma}, [g^{-1}]_{\Gamma}\},$$

with admission under the frozen exact translation-length predicate $\ell(g) \leq 21/10$. A valid owner record therefore needs more than a word, trace, matrix, or approximate length. It needs a full surface-group conjugacy disposition, a maximal-root or no-proper-power disposition, an external inversion-pair assignment, a cutoff proof, and a completeness account for the candidate universe. Powers are repetitions rather than new primitive owners. A self-reciprocal class is a special internal relation and does not replace the external inverse-pair convention.

The two project objects originate in a substantial but heterogeneous literature. Nazarenko (2013) [14] supplies the compact genus-two octagon-family and generator context from which the frozen control is drawn. Aigon-Dupuy et al. (2005) [1] provide peer-reviewed family-level context for genus-two hyperbolic octagons and Fuchsian descriptions. For the target, Aurich et al. (1991) [2] provide regular-octagon matrices, a length relation, and a periodic-orbit enumeration precedent, while Katz et al. (2016) [12] provide arithmetic-Fuchsian and quaternion-order context for the Bolza surface. Grácio and Sousa Ramos (2010) [7] connect symbolic dynamics and fundamental-group words to genus-two length-spectrum computation. These contributions support objects and candidate-generation contexts; they are not treated as completed P33 owner censuses.

1.2 Research question

The frozen research question is:

Research question. Can exact full-conjugacy, inversion-pair, primitivity, and completeness certificates close both frozen owner censuses at the inherited cutoff $\Lambda = 21/10$ beyond the already-known coarse support?

Stage 1 does not answer this question through execution. It addresses the prior methods question: what architecture is supported by the verified, frozen literature, what semantic contract must be shared across heterogeneous surface-specific proof routes, and which obligations remain open before computation may begin?

The inherited cutoff was historically target-blind. The statements that the Bolza target is empty below $21/10$ and that the control has a primitive owner below the same cutoff are retained only as unverified inherited architecture-only assumptions. If a separately authorized replay verifies the target's strict systolic inequality with passage-adequate hypotheses, then BP may certify an empty bounded domain; if a separately authorized replay verifies the control witness and its primitive-owner obligations, then CP must include the corresponding owner. Neither antecedent is established by the present support work. The common cutoff must not be retuned, and these conditional directions support no empty-versus-nonempty scientific comparison, arithmetic inference, A0/A1/A2 closure, Route-A credit, or Route-B conclusion.

1.3 Bounded contribution

The contribution is a review-adjudicated certificate-methods design based on semantic commonality without forced implementation identity. Bolza and control producers may use different representations, algorithms, and theorem routes, but must emit one semantic schema for independent checking. This prose architecture does not establish producer feasibility, theorem applicability, validator termination, owner admission, novelty, or priority.

2 Literature and Theoretical Framework

2.1 Frozen geometry, arithmetic context, and candidate generation

The control is the single source-locked object NAZARENKO-EXP-OCTAGON-G2, not a representative of all nonarithmetic surfaces. Nazarenko (2013) [14] supports the construction and generator layer, and Aigon-Dupuy et al. (2005) [1] support the broader peer-reviewed octagon-family setting; neither source by itself proves the project specialization’s arithmetic status, exact systole, or primitive-owner census. The frozen specialization is $u = a = e^{-1/10}$, $\alpha = \pi/4$, $x = u^2 = e^{-1/5}$, $\Delta = (1 - u^2)(2u^2 - 1)$, and $N = -\Delta^{-1/2}$. Its proof-bearing ordered generators are

$$g_0 = N \begin{pmatrix} u & u^2 + i(1 - u^2) \\ u^2 - i(1 - u^2) & u \end{pmatrix}, \quad g_1 = N \begin{pmatrix} u & (1 - u^2) + iu^2 \\ (1 - u^2) - iu^2 & u \end{pmatrix},$$

with $R = \text{diag}(e^{i\pi/4}, e^{-i\pi/4})$, $g_2 = Rg_0R^{-1}$, and $g_3 = Rg_1R^{-1}$, under the presentation

$$\langle g_0, g_1, g_2, g_3 \mid g_0g_1^{-1}g_2g_3^{-1}g_0^{-1}g_1g_2^{-1}g_3 = I \rangle.$$

The producer input uses $\ell(g) = 2 \operatorname{arcosh}(|\operatorname{tr} g|/2)$, exact admission $\ell(g) \leq 21/10$, and the finite-domain centre guard $|\alpha_g|^2 \leq 20000$. The canonical generator-object bytes are `papers/28-bolza-magnetic-flow/results/round7_nonarithmetic_control_matrices.json`, SHA-256 `a900749b6905a5f324c2e2670363ec1bc9480481f3f5aa1240ed0ebbee55e6ca`; the bound finite certificate is `papers/28-bolza-magnetic-flow/results/round8_control_finite_ball_certificate.json`, SHA-256 `c1bf68a8a1485665680dba01d0012fb691c7ca1a795e36334639e34bbbdbcb1f`. CP must consume those exact values and digests. This is a transcription of accepted upstream locks, not a new replay, theorem, or census.

The control’s nonarithmeticity remains a bounded multi-source and inherited-project input. Takeuchi (1975) [20, 21] supplies an arithmetic-Fuchsian trace-field criterion, with the official 2006 correction cited as a separate record; this metadata binding neither supplies a passage locator nor strengthens the criterion’s project-specific application. Popescu (2024) [15] supplies a Lindemann-Weierstrass ingredient relevant to the inherited expression containing $\exp(-1/5)$. The project-specific inference would require those ingredients to be applied to the exact frozen trace formula; this Phase-6 revision neither reconstructs nor newly proves that chain.

The target is similarly treated through bounded complementary context. Aurich et al. (1991) [2] provide regular-octagon periodic-orbit and matrix context, and Katz et al. (2016) [12] provide exact arithmetic and quaternion-order context for Bolza. Jenni (1984) [10] remains PLAUSIBLE, page-unpinned, and context-only in the frozen verifier; it is not used here to assert an exact systole theorem or formula. Schmutz (1993) [17] supplies broader extremal and systolic context without independently validating the project replay inequality. Thus object identity, arithmetic characterization, systolic context, and below-cutoff owner closure remain separate evidence surfaces.

2.2 From candidate words to owner semantics

Candidate generation and ownership require different proof objects. Aurich et al. (1991) [2] and Grácio and Sousa Ramos (2010) [7] support pathways from exact or symbolic group data to length-spectrum candidates. Such candidates are not unique owners merely because they share a length, trace, homology class, literal word, or matrix representation. Under the frozen design, those quantities may filter or organize work, but none is a substitute for full-group conjugacy.

Primitive and reciprocal semantics must also remain distinct. Cherubini et al. (2022) [3] connect primitive closed-geodesic counting to primitive root-conjugacy classes and distinguish primitive classes from repetitions. Erlandsson and Souto (2024) [6] study reciprocal geodesics, including the special case in which a class is conjugate to its inverse. P33 applies external inversion pairing to every oriented class, including non-self-reciprocal classes. Consequently, full conjugacy, maximal-root status, self-reciprocity, external inversion pairing, and repetition accounting require independently tagged dispositions.

2.3 Algorithmic components under heterogeneous inputs

The frozen corpus contains strong component-level algorithmic precedents but no finished cross-surface implementation. Voight (2009) [22] develops exact fundamental-domain, presentation, reduction, and word-problem methods for suitable cofinite Fuchsian input. Despré et al. (2023) [4] give a terminating Dirichlet-domain method from a hyperbolic surface polygon with side pairings, under a different computational input setting. Their applicability cannot be silently unified for the frozen algebraic target and source-locked transcendental control.

Epstein and Holt (2006) [5] establish a general conjugacy solution for word-hyperbolic groups and include a positive-conjugator pathway; the corrected frozen page range is 287–305. Lysenok (1990) [13] provides root-extraction and related algorithmic solvability in hyperbolic groups. These results support feasibility classes. They do not instantiate project-specific constants, canonical negative evidence, exact generator encodings, hash-stable serialization, or proof that both frozen presentations satisfy every required hypothesis.

The design implication is narrower than a transferred theorem. Each surface-specific producer must eventually bind its own exact representation, theorem identifiers, implementation versions, and applicability proof. Interoperability need not force those internals to be the same. What must be common is the meaning of the claims that leave the producer.

2.4 Rigorous predicates and producer-validator separation

Strohmaier and Uski (2013, corrected 2018) [18, 19] illustrate a separation among bounded computation, error control, and completeness reasoning for spectral objects on hyperbolic surfaces; their 2018 correction is cited separately, remains confined to its recorded scope, and their determinant endpoint is outside P33. Johansson (2017) [11] presents arbitrary-precision midpoint-radius arithmetic with explicit error radii. Rump (2010) [16] surveys rigorous verification using floating-point computation. These works support proof-bearing enclosure discipline for appropriate numerical predicates, but interval arithmetic does not decide group conjugacy or primitivity.

Hoffman et al. (2016) [9] provide a nearby example of separating approximate hyperbolic-geometry candidates from rigorously validated outputs, although their objects are hyperbolic three-manifolds rather than the present closed surfaces. Hales et al. (2017) [8] provide a large-scale precedent for production computation accompanied by independently checkable formal artifacts. P33 uses these as architectural precedents only. The literature does not validate an unbuilt P33 producer or require that P33 adopt any one proof-assistant or numerical library.

Within the frozen 20-source corpus, the closest architectural comparators are the approximate-candidate-to-rigorous-output separation represented by Hoffman et al. and the production-artifact-to-independent-checking pattern represented by Hales et al. The shared features are an untrusted producer, a stable evidence object, explicit predicates, and a checker that need not reproduce the producer’s search. P33’s narrower addition is a mathematical owner-semantics layer for two surface-specific producers: the common record distinguishes full-group conjugacy, maximal roots and primitivity, external inversion pairing, self-reciprocity, repetitions, cutoff disposition, termination, and completeness while permitting different internal mathematics. This is a closest-work comparison only within the bounded frozen corpus. No external novelty search was performed, so the comparison establishes neither field-general firstness nor priority, and the manuscript makes no such claim.

3 Executed Methodology

3.1 Closed-corpus design

The field-facing method was a closed-corpus evidence synthesis. It first froze the two source-locked surfaces, unit-speed physical base-geodesic time, $b = 1/2$, the signed-field even subsequence, the inverse-paired primitive-owner rule, $\Lambda = 21/10$, the result taxonomy, and fail-closed states. It then screened

a bounded corpus of 20 retained sources and recorded, for each record, identity, verification status, admissible use, exclusion boundary, and locator status. Source-effect rows were aligned by mathematical function and synthesized into object, candidate-generation, conjugacy, root-decision, owner-semantics, rigorous-predicate, and producer-checker themes. Architectural inferences were separated from literature-supported facts, and adversarial, citation-integrity, ethical, and editorial checks were retained as provenance rather than as scientific evidence. The complete numbered workflow history and its checkpoints remain in the repository path manifest; they are not used as the reader-facing explanation of the method.

Stage-4-prime support work on 4 September 2026 performed only commit-pinned artifact replay, bounded identifier-endpoint replay, correction-metadata finalization, contract emission, and deterministic synthetic-conformance validation. It added no source beyond the frozen twenty and verified no source passage: all 48 uses retain `anchor=none` and `claim_to_passage=INCONCLUSIVE`. Two valid and twelve invalid files are synthetic fixtures for the notes-side harness, not surface records or evidence of a production validator. No geodesic enumeration, conjugacy query, root query, systole proof, primitive-owner census, scientific experiment, result refresh, or canonical promotion occurred; the findings concern support provenance and open production obligations, not newly computed dynamics.

3.2 Source verification and evidence controls

The inventory contains 20 sources: nine S2_VERIFIED, ten VERIFIED, and one PLAUSIBLE; 18 were conservatively counted as peer reviewed. A bounded identifier-endpoint replay on 4 September 2026 retained all twenty identities and finalized exactly 48 source-use rows. It retained no full-text body and produced zero exact passage or hypothesis locators, so every row is explicitly bounded-unavailable and remains `claim_to_passage=INCONCLUSIVE`. S2_VERIFIED establishes record identity and metadata, not theorem- or passage-level support; the evidence matrix continues to separate admissible contributions from stronger excluded uses.

Correction metadata is now dual-bound at every affected use while locator boundaries remain unchanged. The Takeuchi record retains its correction binding (Takeuchi, 1975) [20, 21], and the Strohmaier-Uski record retains its 2018 correction binding (Strohmaier and Uski, 2013, corrected 2018) [18, 19]. Epstein and Holt (2006) [5] retains pages 287–305. Jenni (1984) [10] remains PLAUSIBLE, page-unpinned, and context-only.

Every literature statement has a visible citation and `anchor:none`; no direct quotation is used. The finalized machine-readable ledger is `notes/stage4_prime_round5_source_use_locator_final.json`, SHA-256 `fa2dd2de6a6a69ad2fe297ff4277cb70e19e0cf8814418a35080e4b0e9ded11f`, with its receipt at `notes/stage4_prime_round5_source_use_locator_receipt.json`, SHA-256 `70a390daf78d56dd335e6137c42d9fede1886db8ada429a073987bceb2842272`. It records, for P33-U01–P33-U48, the interface, 4 September 2026 retrieval date, exact identifier query, returned identifier or unavailable-total receipt, screening disposition, hypotheses, correction state, applicability boundary, and prohibited stronger transfer. The replay checked only the frozen identifier endpoint and at most a 4096-byte response prefix; it retained and parsed no full-text body. Consequently 48 of 48 uses are EXPLICIT_BOUNDED_UNAVAILABLE, zero have an exact passage locator, and 48 of 48 remain INCONCLUSIVE. The five correction-affected uses are dual-bound to their base and correction keys, but that metadata binding is not passage verification. No systematic source-level retraction or conflict-of-interest audit was run.

3.3 Synthesis and adjudication method

The synthesis was limited to eight manifest claims. Review comments informed architecture, article positioning, asymmetry, and AI provenance; requests requiring retrieval, source finalization, science, or implementation remain limitations. The design asks whether separate exact routes can share owner semantics and whether an independent validator can reject unsupported claims. A positive design answer is not an implementation answer.

4 Review-Adjudicated Proof and Method Architecture

4.1 Two surface-specific exact proof-producer contracts

The architecture defines two prospective producer roles.

Bolza proof-producer (BP) population-completeness contract. The notes-side contract `notes/stage4_prime_round5_support/bp_enumeration_contract.json`, SHA-256 `d8ad8be0f1c8242085914ca9557879545efe312d1e2d7fe397eee3546c963073`, and its distinct ledger schema `notes/stage4_prime_round5_support/bp_coverage_ledger.schema.json`, SHA-256 `8f86ba896308c087097f8f0bcf45678d8ff8b51cd7b073b8bf0c5a79c65a4054`, bind the prospective BP input to `papers/28-bolza-magnetic-flow/results/round4_bolza_group_certificate.json`, SHA-256 `e3e6c486c66116dc6fe9fdd054c2fce9d4b1a58318f56d1656f6db168c807eca`. BP’s empty-domain path is strictly conditional: only a separately valid, passage-adequate replay of $\text{sys}(S_{\text{Bolza}}) > 21/10$ may terminate it as empty; failure, missing hypotheses, or digest drift remains `UPSTREAM_REPLAY_CONTRADICTION` or not evaluable. The contract fixes canonical input, theorem/algorithm-version slots, exact cutoff comparison, deterministic order, included and rejected digest domains, termination witness, distinct coverage digest, complete unresolved ledger, and independent population-bound replay. The theorem and algorithm versions remain unavailable, no observed coverage digest is emitted, and no producer, enumeration, owner quotient, or census was run.

Control proof producer (CP) population-completeness contract. The separate notes-side contract `notes/stage4_prime_round5_support/cp_enumeration_contract.json`, SHA-256 `f96b1e81baeacb4e6d1dda400b36e7c8da45eb50c43d2c80d95c1c5c1e41c621`, and ledger schema `notes/stage4_prime_round5_support/cp_coverage_ledger.schema.json`, SHA-256 `696a3911e241ab14ad1eb53a20e7bf6239a93c4b90d5656c8c5d9295f0685eab`, bind prospective CP input to the frozen `NAZARENKO-EXP-OCTAGON-G2` generator and finite-ball certificate bytes. They specify FIFO breadth-first order from the identity through $g_0, g_1, g_2, g_3, g_0^{-1}, g_1^{-1}, g_2^{-1}, g_3^{-1}$, exact normalized-state deduplication, the centre guard $|\alpha|^2 \leq 20000$, exact admission $\ell(g) \leq 21/10$, queue-exhaustion and outgoing-edge termination, separate included/rejected digest domains, a distinct CP coverage digest, and a complete unresolved ledger. CP may retain its own representation and proof route, but a checker must reconstruct its bound and digests. The contract is declarative only: theorem and algorithm versions, production proof payloads, observed coverage digest, producer run, and owner census remain absent.

“Exact proof producer” requires checkable evidence under a declared proof type; it does not assert existing software. Producer proofs may differ, while their semantic conclusions remain comparable.

4.2 One common semantic owner-certificate schema

The proposed common schema is a versioned semantic envelope around producer-specific evidence. It is a design specification, not a serialized artifact already frozen for execution. Its minimum record families are:

Record family	Required semantic fields	Fail-closed purpose
Run header	schema version; surface ID; producer and proof-type IDs; input, theorem-version, implementation, and correction-provenance digests; frozen clock, subtype, owner rule, and cutoff	binds every claim to one exact prospective run and prevents silent input or correction drift

Record family	Required semantic fields	Fail-closed purpose
Candidate	stable candidate digest; producer-normalized representation; enumeration provenance; exact or proof-bearing cutoff disposition	distinguishes candidate generation from owner admission
Conjugacy	ordered pair of oriented-class candidates; exactly one positive, negative, or unresolved disposition; positive conjugator or producer-specific negative/canonical proof payload	prevents filters, timeouts, or failed searches from becoming nonconjugacy proofs
Root/primitivity	maximal-root representative and exponent, or independently checkable no-proper-power payload; primitive/repetition disposition	prevents a power from minting a primitive owner
Inversion and reciprocity	oriented class ID; inverse-class link; external owner-pair ID; separately proved self-reciprocal flag	applies inverse pairing universally while preserving the reciprocal special case
Owner and repetition	deterministic owner ID; member oriented classes; primitive representative; all admitted repetitions mapped to that owner	keeps multiplicity and repetition separate from owner credit
Termination and completeness	theorem-bounded candidate-universe descriptor; termination witness; resolved/unresolved totals; coverage digest; resource-stop state	distinguishes complete, bounded-incomplete, and not-evaluable outcomes
Validation	validator version and digest; per-predicate decisions; rejected incompatibilities; accepted/rejected fixture-set digest	prevents a producer from self-certifying its summary

Canonical records use UTF-8 in NFC form, no byte-order mark, LF line endings, byte-lexicographically ordered object keys, prescribed array order, and no insignificant whitespace. Integers use unsigned or explicitly signed base-10 strings without leading zeros; a rational uses the canonical byte-order object $\{\text{den}, \text{num}\}$, where den is positive, num is signed, and the two integers are coprime; floating-point numbers, NaN, infinities, duplicate keys, and unknown fields are forbidden. The record digest is SHA-256 of the ASCII domain prefix `P33-OWNER-CERT`, one zero byte, the schema version, one zero byte, the proof-registry digest, one zero byte, and the canonical record bytes. Records are ordered by `surface_id`, `record_type`, and record digest; owner members use the deterministic rule stated below. Compatibility requires exact equality of both `schema_version` and `proof_registry_digest`. A migration is never implicit: it must have its own version and digest, a total source-to-target transformation contract,

declared failure states, preserved source bytes, and complete parser, predicate, owner, coverage, and digest revalidation of every transformed record. The byte rules have now been exercised only by two valid and twelve invalid canonical synthetic fixture files under the notes-side conformance harness. Their matching deterministic dispositions do not emit a scientific execution digest and do not establish a production owner-certificate schema, adapter, predicate kernel, or validator.

Positive evidence requires a replayable producer-appropriate witness. Negative evidence requires a theorem-backed canonical or exhaustive payload; failed search, timeout, cap, or numerical nonmatch is not a certificate. The validator may dispatch tags to independent BP and CP adapters, so common semantics do not imply common solver code.

The paper-level common contract is P33-OWNER-CERT/1 with proof registry P33-PROOF-TYPES/1. Its closed allowed top-level field set is `schema_version`, `proof_registry_digest`, `surface_id`, `producer_id`, `run_id`, `record_type`, `candidate_id`, `producer_representation`, `enumeration_provenance`, `oriented_class_digest`, `primitive_root_digest`, `root_exponent`, `inverse_class_digest`, `owner_id`, `owner_member_digests`, `cutoff`, `cutoff_disposition`, `proof_type`, `proof_payload`, `input_digest`, `theorem_version_digest`, `implementation_digest`, `correction_provenance_digest`, `clock_id`, `subtype_id`, `owner_rule_id`, `termination_witness`, `coverage_digest`, `unresolved_count`, `validator_version`, `validator_digest`, `fixture_set_digest`, `predicate_decisions`, `rejected_incompatibilities`, and `state`. The record family determines the mandatory subset described in the preceding schema table; unlisted fields, missing mandatory fields, or unrecognized enum values fail closed. The closed `record_type` enum is `run_header`, `candidate`, `conjugacy`, `root`, `inversion`, `owner`, `repetition`, `termination`, `coverage`, or `validation`; `surface_id` is `BOLZA-SOURCE-LOCK` or `NAZARENKO-EXP-OCTAGON-G2`. The closed `state` enum is `declared`, `parsed`, `predicate_checked`, `accepted`, `rejected`, `bounded_incomplete`, or `not_evaluable`. The proof registry admits only `exact_conjugator`, `canonical_conjugacy_normal_form`, `maximal_root`, `no_proper_power`, `systolic_primitive`, `exact_cutoff_comparison`, `exact_trace_comparison`, `conjugacy_to_inverse`, `termination_measure`, and `coverage_replay`; each payload must name its input digests and supply the exact witness consumed by the correspondingly named predicate. State moves are declared to `parsed` to `predicate_checked` and then to exactly one terminal state; only the checker may derive the final move. A complete run is rejected if any conjugacy, root, cutoff, inverse, owner, termination, or coverage disposition is unresolved; if a proof type cannot be dispatched, the run is `not_evaluable`. A primitive record cannot have exponent greater than one, a repetition cannot mint an owner distinct from its primitive root's owner, and a self-reciprocal record requires separate conjugacy-to-inverse evidence plus its external inverse link. Failed termination or coverage, a missing correction binding, duplicate canonical owner IDs, digest drift, or an unrecognized proof type precludes acceptance. A synthetic proof-registry snapshot and fourteen canonical conformance fixtures now exercise this manuscript-level vocabulary, but they are notes-side test artifacts only. No production producer, owner-certificate schema implementation, adapter, predicate kernel, validator, or scientific record has been implemented or run.

4.3 Independent validator contract

The notes-side trust graph is frozen at `notes/stage4_prime_round5_support/trust_graph.json`, SHA-256 34ab38b26566ba6cc80ef1b2fdf266d7e7fe3f47af5129756ebca737611895fc. Its nodes distinguish BP, CP, their adapters, parser and predicate kernels, a fixture oracle, theorem encodings, libraries, and accountable implementers; shared schema, digest, and general-purpose-library dependencies are classified separately from disqualifying producer-decision-code reuse. The synthetic expected outcomes and provenance are recorded in `notes/stage4_prime_round5_support/fixture_oracle_manifest.json`, SHA-256 0aadbe0af06acad88dcab573b3e3206bac ef20ec237aa882568509233ae4d044. That oracle is procedurally separate from producer output but was not independently authored by a second human or runtime, so production independence is not

established. The component record `notes/stage4_prime_round5_support/component_build_provenance.json`, SHA-256 `56ed464ffd96fb4f8c3f604e8f94e297a1481eefd5aea52fead9f388a1fd0824`, reports zero available production components; BP, CP, both adapters, the parser, and predicate kernels remain `UNAVAILABLE_COMPONENT_NOT_IMPLEMENTED`. The static exclusion audit at `notes/stage4_prime_round5_support/producer_code_exclusion_audit.json`, SHA-256 `73d6f7f9f33989a08a8ddc4123d22292e78f68d27b729f0475b2c0f9603b5a86`, is therefore `NOT_EVALUABLE`. No absent source-tree, build-environment, theorem-encoding, or build hash is invented, and no validator-independence claim is made.

The notes-side fixture corpus now contains exactly two valid canonical synthetic records and twelve invalid synthetic records covering malformed schema, unknown proof type, altered digest, unsupported negative decision, primitive/power conflict, missing inverse link, false reciprocity, duplicate owner, unresolved cutoff, incomplete coverage, invalid termination, and hash mismatch. The deterministic receipt `notes/stage4_prime_round5_support/serialized_fixture_validation_receipt.json`, SHA-256 `294a80fe696be66584e13377c446cf536982bd2a9cfc1807277ad05da09c0b21`, records fourteen of fourteen outcomes matching the separately frozen synthetic oracle with zero harness failures. These bytes test only canonical serialization and fail-closed conformance against the synthetic registry snapshot; they are not surface records, producer outputs, owner-census results, or evidence that a production validator exists.

The serialized fixtures are synthetic conformance examples, not scientific surface records. The valid BP and CP files use `run_id=synthetic` and private proof tags mapped to the common fields for surface, candidate, oriented class, primitive root, inverse link, owner, cutoff, proof type, coverage, and unresolved count. The harness accepts canonical bytes, dispatches only recognized synthetic registry tags, checks required links and digests, and reaches a closed expected disposition. The twelve invalid files each isolate one declared fault and must remain rejected or not evaluable; no producer label, approximate equality, or another record’s payload may repair them. The fourteen-file receipt demonstrates deterministic agreement with the frozen synthetic oracle, not producer soundness, theorem applicability, predicate-kernel independence, population completeness, or a Bolza/control census.

4.4 P33-RC-1 reorganized as a three-package fail-closed gate

The seven original obligations remain unchanged and unimplemented. Revision-1 reorganizes them so that shared semantics are not confused with shared implementation.

Package	Original obligations retained	Prospective closure evidence	Current status
A. Producer-specific soundness	1 representation applicability; 2 full conjugacy; 4 root and primitivity; producer side of 5 termination and completeness	for BP and CP separately: exact input encoding, named theorem/algorithm versions, applicability proof, positive and negative proof types, maximal-root logic, candidate bound, termination proof	unimplemented

Package	Original obligations retained	Prospective closure evidence	Current status
B. Common-schema interoperability	3 external inversion pairing; 6 deterministic artifacts; shared side of 5 completeness	versioned field schema, canonical ordering, proof-type registry, correction provenance, serialization and hash domain, repetition rules, coverage and unresolved ledgers	unimplemented
C. Independent validation	7 independent validation; checker side of 2, 4, 5, and 6	independent validator and proof adapters, predicate table, incompatibility checks, accepted/rejected fixtures, replay receipts	unimplemented

The underlying count remains zero of seven implemented obligations. This report supplies a more precise prospective contract, not closure evidence. If either producer lacks a sound exact conjugacy method, or if a negative disposition cannot be independently certified, the lawful fallback remains NOT_EVALUABLE_CONJUGACY_METHOD_UNAVAILABLE. If a resource stop prevents complete coverage while some valid records exist, the output must be bounded-incomplete rather than a negative theorem.

The literature supports the three-package architecture only at component and precedent level. Voight (2009) [22] and Despré et al. (2023) [4] support different domain or presentation pathways. Epstein and Holt (2006) [5] and Lysenok (1990) [13] support conjugacy and root-decision components. Cherubini et al. (2022) [3] and Erlandsson and Souto (2024) [6] motivate separate primitive, repetition, reciprocal, and inverse-pair semantics. Strohmaier and Uski (2013, with the separately cited 2018 correction) [18, 19], Johansson (2017) [11], and Rump (2010) [16] support rigorous predicate and enclosure discipline. Hoffman et al. (2016) [9] and Hales et al. (2017) [8] support the broader producer-validator pattern. None supplies the missing P33 implementation or scientific result.

4.5 Audit interpretation of the prospective contract

The three-package organization is intended to make later evidence auditable without pretending that prose is executable. Package A is evaluated separately for BP and CP. For each producer, a future reviewer would need to identify the exact mathematical input, the representation of generators and words, the theorem or algorithm invoked for every decision, and the hypotheses that connect that theorem to the frozen surface. A producer label, a successful program exit, or an approximate numerical match would not meet this burden. Each positive decision would need a replayable witness appropriate to its proof type; each negative decision would need canonical, exhaustive, or otherwise theorem-backed evidence. If a producer can generate candidates but cannot justify a negative full-group conjugacy decision, it cannot report a complete owner set. The contract therefore treats implementation availability and mathematical soundness as distinct questions.

Package B fixes owner semantics across the producer boundary. Let $d(g)$ be the canonical digest of an oriented full-group conjugacy class after its conjugacy predicate has passed, and let $d(g^{-1})$ be computed independently under the same rule. If a separate conjugacy-to-inverse proof passes, the self-reciprocal owner has the deduplicated singleton member list $[d(g)]$, cardinality one, and an inverse link to itself. Otherwise the owner has the two distinct member digests $[\min(d(g), d(g^{-1})), \max(d(g), d(g^{-1}))]$, cardinality two, in byte-lexicographic order, with reciprocal inverse links. The owner identifier is

SHA256(P33-owner-v1 ||| surface-id ||| member-count ||| ordered-member-bytes),

where each separator and field encoding follows the canonical-byte contract. Duplicate candidate rows are removed before this derivation and cannot change the member list or identifier. A repetition records its primitive-root digest and the already derived root owner identifier; it never mints an owner. Equal length, trace, word, homology, or literal matrix data cannot set self-reciprocity or merge owners. These rules fix membership, deduplication, inverse links, and owner IDs without asserting that any owner has been computed.

Interoperability also requires explicit treatment of incomplete information. Positive, negative, and unresolved dispositions are not interchangeable. A timeout, cap, failed search, missing adapter, unknown proof tag, or hash mismatch must remain visible and cannot be coerced to a negative answer. A run claiming completeness would have to account for every theorem-bounded candidate and every derived oriented class, with no unresolved conjugacy, root, cutoff, inversion, or owner relation. A bounded search that returns some valid records but lacks coverage may still be useful, yet its lawful status is bounded-incomplete. If an exact conjugacy method is unavailable for either frozen presentation, the contract preserves `NOT_EVALUABLE_CONJUGACY_METHOD_UNAVAILABLE`. This status is an execution limitation, not a theorem that the corresponding geodesic or owner does not exist.

Package C’s intended rules are now exercised by a notes-side synthetic harness: two canonical valid files and twelve one-fault invalid files have frozen expected dispositions, and the deterministic validation receipt reports fourteen of fourteen matches. The cases cover altered provenance digests, unrecognized proof types, unsupported negative decisions, primitive/power conflict, missing inverse links, false reciprocity, duplicate owners, unresolved cutoffs, incomplete coverage, invalid termination, malformed schema, and hash mismatch. This is evidence about the synthetic conformance contract only. Because BP, CP, adapters, parser, production predicate kernels, and a second independently authored oracle are unavailable, the run cannot demonstrate producer-code exclusion or production-validator independence and cannot certify either surface census.

The contract separates local record validity from population completeness. A conjugacy witness may be correct for one pair while the candidate universe is incomplete; a root witness may be correct while inverse pairing is absent; and individually sound owner records may omit an admissible owner. Conversely, an empty bounded output is an empty-universe certificate only if its candidate bound, length predicate, termination argument, correction provenance, and complete unresolved ledger all replay. The inherited Bolza-side empty direction is therefore an unverified architecture-only assumption: if a separately authorized, passage-adequate strict-systole replay succeeds, it may trigger BP’s conditional empty-domain branch; otherwise the branch remains not evaluable. No empty output, synthetic fixture, or contract file establishes that scientific antecedent.

Finally, every prospective run would need a state transition that can be reconstructed from the evidence. Producer creation, schema serialization, validation, scientific interpretation, and roadmap interpretation are separate events. A validator acceptance could authorize reporting a per-surface certificate status only under a later gate; it could not automatically award Route-A credit or open Route B. Rejection or non-evaluability would report the failed obligation without strengthening a geometric conclusion. This manuscript provides the vocabulary and failure semantics for such an audit. It does not create schema bytes, fixtures, software, certificates, owners, completeness proofs, or a route verdict, and all seven P33-RC-1 obligations remain unimplemented.

5 Evidence-Synthesis Findings

5.1 Object support without owner identification

The frozen literature supports genus-two octagon objects, Bolza context, and candidate-generation precedents, but it does not itself identify unique primitive inverse-paired owners. Nazarenko (2013) [14] and Aigon-Dupuy et al. (2005) [1] bound the control-family context. Aurich et al. (1991) [2], Katz et al. (2016) [12], and Grácio and Sousa Ramos (2010) [7] bound complementary target and candidate-generation contexts. No cited source is converted into a project-level full-conjugacy, maximal-root, inverse-pair, or

completeness certificate.

5.2 Heterogeneous exact producers are compatible at the semantic layer

The synthesis supports a conditional design: two sound surface-specific proof producers may be acceptable if they emit one common semantic owner-certificate schema that an independent validator checks. This conclusion removes a false necessity identified in review. It does not claim that either producer is available, that both exact input models have been selected, or that one validator has been implemented. The common layer standardizes meanings and admissible evidence states; it does not standardize the mathematics inside each producer.

5.3 The frozen-cutoff asymmetry is material

At $\Lambda = 21/10$, P33 treats both cutoff directions as unverified inherited assumptions, not as a design fact or a new census. The target direction is conditional: if a separately frozen, passage-adequate Bolza source-and-proof record is valid and its exact strict-systole comparison replays successfully, then the below-cutoff candidate universe is empty. The control direction is also conditional: if the separately frozen control certificate and primitive witness are valid and replay successfully, then at least one below-cutoff primitive owner must be represented. P33 has not closed either source-to-proof chain at passage level, so claim-to-passage faithfulness remains *INCONCLUSIVE*. These conditionals may parameterize only fail-closed producer obligations and upstream-contradiction checks; they do not establish an empty-versus-nonempty comparison, distinguish arithmetic from nonarithmetic geometry, or license a formal A0 verdict, A1 closure, positive arithmetic A2 status, or Route-B conclusion. The cutoff remains target-blind and must not be retuned after the inherited directions became known.

The cutoff is therefore preserved without post-hoc normalization. The target still needs a valid completeness and empty-universe certificate under its producer contract, but that replay does not create a new comparative finding. The control still needs exact conjugacy, primitive-owner, inverse-pair, cutoff, and completeness closure, and its inherited witness does not establish the rest of the universe.

5.4 Contribution and noncontribution

The achieved contribution is an interoperable exact-certificate methods design for one frozen target/control pair. It is not a completed owner census, validated software method, arithmetic comparison, magnetic comparison, determinant calculation, novelty assessment, exhaustive literature review, impossibility result, or owner no-go. Component nonclosure means that execution is not presently warranted under the frozen proof standard; it does not mean execution can never succeed.

6 Reproducibility and Prospective Execution Interface

6.1 What is reproducible now

The Stage-1/Stage-2 audit trail is commit-retrievable at:

https://github.com/maris205/hilbert-polya-structure/tree/337994b72bd14c7ffbc1f01a6a9b878784df7694/flow_systems/papers/33-bolza-control-matched-census. The complete manifest is `notes/stage4_prime_round5_artifact_inventory_final.json`, SHA-256 `c79ef8b83679d0e9238d19446c27e03a0c9ca0b12b5d23c6f19ed8da63022c6e`, with receipt `notes/stage4_prime_round5_artifact_inventory_receipt.json`, SHA-256 `6b76a0550ad14961c9c4fcdf0f8f369d8aee4722224a6fb5fdb6ae4fd2ef596`. Its selection rule over-covers every regular `notes/stage1_*` and `notes/stage2_*` file named by the availability statement while excluding the distinct `stage2_5_*` audit family. Exactly 43 of 43 rows record the repository-relative path, SHA-256, byte count, media or schema type, explicit unversioned-current-bytes state, local access state, commit-membership state, raw commit URL, HTTP result, and replayed remote digest and byte

count; all 43 are exact matches at commit 337994b72bd14c7ffbc1f01a6a9b878784df7694. Access still requires repository read permission and checkout or retrieval of that commit. The manifest provides exact provenance for existing bytes, not a persistent-archive claim, mathematical validation, or evidence that an omitted or unavailable artifact exists.

Reproducibility here means auditability of the frozen evidence trail, scope, citation closure, and manifest compliance. It is not computational reproducibility of the unimplemented method.

6.2 What a future execution freeze must add

A later, separately authorized phase would need to freeze BP and CP representations independently; exact theorem and implementation versions; applicability proofs; a byte-exact schema and proof-type registry; cutoff and length predicates; positive and negative evidence formats; canonical ordering and hash domain; correction provenance; resource limits and status transitions; an independent validator; and accepted/rejected fixtures. Only after those materials pass review could an execution produce a complete, bounded-incomplete, or not-evaluable census status.

Validated numerical methods may support cutoff or sign predicates where their hypotheses apply. Johansson (2017) [11] and Rump (2010) [16] support disciplined enclosure methods, but additional precision cannot prove nonconjugacy, maximal roots, or candidate completeness. The interface must keep numerical evidence subordinate to the exact group-theoretic proof type it is actually qualified to check.

6.3 State separation

Three axes must remain distinct in future reporting:

1. **Execution status:** not run, rejected at freeze, bounded-incomplete, not evaluable, or completed under a frozen contract.
2. **Scientific content:** per-surface owner and completeness outcomes, only if actually certified.
3. **Roadmap interpretation:** Route-A or Route-B assessment, only under a separately authorized roadmap gate.

This separation prevents a well-designed schema from being misreported as a scientific result and prevents an execution failure from being misreported as a theorem about the surfaces.

7 Discussion and Implications

7.1 Methodological implication

Interoperable evidence need not originate from identical machinery. A common semantic contract protects the meaning of conjugacy, primitivity, inversion, completeness, and failure while permitting producer-specific mathematics. Negative evidence is first-class: failed searches do not prove nonconjugacy, no-root status, or candidate completeness. The schema exposes these distinctions so validation can fail closed.

7.2 Scientific implication of the cutoff

The frozen target-control pair remains useful as an interface stress test because its representations may demand different proof routes. It is not a clean arithmeticity experiment. The target-empty and control-nonempty directions are unverified inherited architecture-only assumptions; if separately replayed with source- and hypothesis-adequate proof records, they may condition different producer duties, but the present contract and synthetic fixtures do not establish either antecedent. The common cutoff remains systole-confounded and the broader control panel remains incomplete, so no empty-versus-nonempty comparison, arithmetic inference, A0/A1/A2 closure, Route-A credit, or Route-B progress follows.

7.3 Route and dynamical-system boundary

The dynamical subtype remains exactly as inherited: unit-speed physical base-geodesic time, $b = 1/2$, and the signed-field even subsequence. The magnetic field remains a model lock rather than a compared outcome. No magnetic period, phase, stability, signed- k , field-sign, determinant, or spectral result is reported.

Within Route A, this report is preparation for a possible A1 ownership/completeness artifact only. It awards no A1 credit because no census or validator has run. The between-surface count contrast remains A0_INCONCLUSIVE_SYSTOLE_CONFOUNDED, the panel remains A0_CONTROL_PANEL_INCOMPLETE, and a formal A0 verdict is prohibited. A2–A4 are not run; positive arithmetic A2 remains absent. Route B is closed. The formal tuple remains UNASSIGNED.

8 Acknowledged Limitations

First, the corpus is bounded, not exhaustive. Search interfaces did not yield auditable global hit totals, and the frozen search did not establish novelty, priority, impossibility, or complete disciplinary coverage. No new search was authorized for this revision.

Second, passage-level support remains materially incomplete after bounded finalization. The exact P33-U01–P33-U48 ledger now records identifier endpoints, dates, queries, receipts, hypotheses, correction state, applicability, and prohibited stronger transfer, but the replay retained no full-text body and supplied zero exact page, section, paragraph, quotation, or hypothesis locators. All 48 uses therefore retain `anchor=none`, `EXPLICIT_BOUNDED_UNAVAILABLE`, and `claim_to_passage=INCONCLUSIVE`. S06 remains PLAUSIBLE and page-unpinned; nine S2_VERIFIED records remain record-level matches rather than theorem validation. Correction dual-binding is metadata provenance, not passage verification.

Third, correction metadata is now represented by exactly two standalone bibliography keys: P33-S03-CORR for the official 2006 Takeuchi correction information and P33-S16-CORR for the 2018 Strohmaier–Uski correction. P33-U08 and P33-U27 bind P33-S03 with P33-S03-CORR; P33-U22, P33-U28, and P33-U37 bind P33-S16 with P33-S16-CORR. No existing bibliography record is rewritten, no distinct DOI is invented for the Takeuchi correction, and the Strohmaier–Uski correction is not generalized beyond its recorded scope. The five dual bindings remain `anchor=none` and `INCONCLUSIVE`; they establish metadata traceability only. Systematic source-level retraction and conflict-of-interest screens were not performed, and no correction metadata strengthens a scientific claim.

Fourth, production architecture remains unimplemented. Notes-side BP/CP enumeration contracts, two coverage-ledger schemas, a trust graph, a synthetic proof-registry snapshot, and a fourteen-file synthetic fixture corpus now exist and pass their bounded deterministic conformance checks. They do not supply a BP or CP producer, production adapter, parser or predicate kernel, theorem-applicability proof, independently implemented oracle, surface candidate universe, conjugacy result, root result, owner record, observed coverage digest, termination proof, or completeness certificate. Production components available remain zero, validator independence remains not evaluable, and the seven P33-RC-1 scientific/production obligations remain unimplemented.

Fifth, the frozen scientific design is asymmetric and limited. The target-empty and control-nonempty directions are unverified inherited architecture-only assumptions, not results. If separately authorized, passage-adequate replays establish their respective antecedents, the directions may condition surface-specific producer obligations; until then the common cutoff remains systole-confounded and the control panel incomplete. The report cannot support an empty-versus-nonempty comparison, a between-surface arithmetic conclusion, A0/A1/A2 closure, Route-A credit, Route-B progress, or generalization to other genus-two surfaces.

Sixth, the review process used separately recorded roles within one AI model family. Procedural separation does not establish statistically independent errors or cross-model calibration. The responsible human author’s authorization does not establish that he performed full-text or source-passage verification.

9 Future Work

Future work requires separate gates. Source finalization could freeze exact passages, apply correction records, clarify S06, and screen retraction and source COI. Implementation design could specify BP and CP encodings, applicability, proof payloads, and termination. Schema and validator gates could freeze exact bytes, semantics, proof tags, status transitions, adapters, and fixtures.

Only after those gates pass should an execution gate replay the inherited locks and attempt the two censuses. Results would need per-surface completeness states and a zero-unresolved ledger before any complete status. A scientifically matched threshold or expanded control panel would be a different design and would require new authorization; it must not be retrofitted into this frozen cutoff.

10 Conclusion

The frozen corpus supports an interoperable certificate-methods architecture, not an executed primitive-owner census. Two surface-specific exact proof producers may use different internal representations and theorem routes. Their outputs can be compared only through one common semantic schema that distinguishes conjugacy, roots and primitivity, external inversion, self-reciprocity, repetitions, cutoff evidence, termination, completeness, and positive or negative replay payloads. One independent validator must check that schema and dispatch producer-specific proof types without trusting producer status.

Revision-1 clarifies this architecture and reorganizes P33-RC-1 into producer-specific soundness, common-schema interoperability, and independent validation. It does not close any implementation or scientific obligation. The frozen-cutoff asymmetry remains explicit, every claim-to-passage binding remains inconclusive, and NOT_EVALUABLE_CONJUGACY_METHOD_UNAVAILABLE remains a lawful fail-closed endpoint.

Phase 6 therefore changes no census, Route tuple, A0 prohibition, positive arithmetic A2 status, Route-B status, formal project claim, canonical manuscript, or canonical result. The only achieved endpoint is a more precise, review-adjudicated methods and evidence-synthesis report.

Declarations

Funding. The author received no funding for this work.

Competing interests. The author declares no competing financial or non-financial interests.

Author contributions. Liang Wang is the sole responsible human author. He provided the research direction, conceptualization, methodological constraints, authorship information, declarations, and phase-gate authorizations; reviewed the bounded outputs; and accepts responsibility for the manuscript's scholarly content.

Ethics approval, consent to participate, and consent for publication. Not applicable. This literature and certificate-design study involved no human participants, personal data, recruitment, intervention, or animal subjects.

Data, materials, and code availability. The exact 43-row Stage-1/Stage-2 artifact inventory is `note s/stage4_prime_round5_artifact_inventory_final.json`, SHA-256 `c79ef8b83679d0e9238d19446c27e03a0c9ca0b12b5d23c6f19ed8da63022c6e`; every row supplies a path, explicit version state, SHA-256, byte count, media/schema type, workspace access state, and exact pinned-commit replay fields. All 43 rows matched commit `337994b72bd14c7ffbc1f01a6a9b878784df7694` on 4 September 2026. The bounded 48-use source ledger and notes-side synthetic conformance artifacts are identified by their own repository paths and hashes in that support package. Repository access is

conditional and no persistent archive is claimed. This manuscript produced no new scientific dataset, geodesic enumeration, experimental output, owner census, production validator, observed coverage digest, canonical-result refresh, or Route result; the fourteen fixture files are synthetic test records only.

AI assistance and verification limitation. OpenAI Codex from the GPT-5 model family assisted the recorded workflow on 2 September 2026 UTC with literature-search support, source-record and metadata checks, evidence synthesis, adversarial and role-based review, deterministic citation and hash checks, and manuscript drafting and restructuring. On 4 September 2026 UTC it also assisted with support-artifact generation, commit-pinned artifact replay, bounded identifier-endpoint replay, correction-metadata preparation, synthetic fixture and oracle preparation, BP/CP contract preparation, and deterministic support validation. The exact backend snapshot was not exposed. Liang Wang supplied the project direction and remains the accountable author; the record does not establish that he personally performed full-text or source-passages verification. The bounded replay retained no full-text body and verified no passage, so all 48 literature uses remain `anchor=none` and `claim_to_passage=INCONCLUSIVE`. AI assistance, human authorization, correction metadata, and synthetic-conformance success do not establish source cleanliness, production-validator independence, theorem applicability, scientific method validity, or a surface result.
