

A Maximal-Monotone Stick–Slip Atlas for the Coulomb Oscillator

HCS Research Program

29 August 2026 (revision 2)

Abstract

We make the scalar Coulomb oscillator unambiguous at zero velocity by freezing the maximal-monotone Sign graph together with a viability rule. For $\dot{x} = v$, $\dot{v} = -\omega^2 x - c\xi$, the static interval is $|x| \leq a_f = c/\omega^2$. Each slip branch is a shifted harmonic oscillator, giving $\dot{E} = -c|v|$, an exact rest half-cycle map, an integer finite-capture formula for $c > 0$, and closed first-turn phases for arbitrary signed velocity. The $c = 0$ harmonic face is separated because it has no capture. This is a source-local nonsmooth-mechanics theorem: it supplies no arithmetic owner, target determinant, or Hilbert–Pólya claim.

1 Inclusion and selection law

Write

$$\dot{x} = v, \quad \dot{v} = -\omega^2 x - c\xi, \quad \xi \in \text{Sign}(v), \quad \omega > 0, \quad c \geq 0, \quad (1)$$

where $\text{Sign}(0) = [-1, 1]$. Put $a_f = c/\omega^2$. At $v = 0$, the selected viability law sticks exactly when $|x| \leq a_f$; an exterior rest releases inward. This convention is part of the model and removes the otherwise ambiguous zero-velocity branch.

Theorem 1 (Global trajectory and energy). *The selected maximal-monotone trajectory exists uniquely for all forward times. Backward uniqueness is not asserted after capture into the sticking set. On every slip interval,*

$$E = \frac{1}{2}(v^2 + \omega^2 x^2), \quad \dot{E} = -c|v|, \quad (2)$$

while on a sticking interval $\dot{E} = 0$.

Proof. For $v > 0$, (1) is the smooth equation $\ddot{x} + \omega^2 x + c = 0$; for $v < 0$ it is $\ddot{x} + \omega^2 x - c = 0$. The Sign graph is maximal monotone, and the viability selection keeps a rest in the closed static interval. Standard one-dimensional maximal-monotone uniqueness then concatenates the smooth slip arcs and the sticking intervals without a Zeno ambiguity. Multiplying the slip equation by v gives (2). $\square$

2 Rest starts and exact capture

Assume $c > 0$. For $x(0) = A > a_f$, $v(0) = 0$, the first motion has $v < 0$, center $+a_f$, and

$$x(t) = a_f + (A - a_f) \cos(\omega t), \quad x_1 = 2a_f - A. \quad (3)$$

If A_k is the signed turning point after the k -th complete moving half-cycle, then

$$A_k = (-1)^k (A - 2ka_f), \quad |A_{k+1}| = |A_k| - 2a_f. \quad (4)$$

Consequently the exact number of moving half-cycles for $A > a_f$ is

$$n = \left\lceil \frac{A - a_f}{2a_f} \right\rceil, \quad (5)$$

and the stopping turn A_n lies in $[-a_f, a_f]$. A rest already in that interval has $n = 0$. Negative rests follow by reflection.

Proposition 1 (Work check). *The first-turn energy drop from a positive rest is $E(A, 0) - E(2a_f - A, 0) = c|A - (2a_f - A)|$, exactly the friction work.*

3 Arbitrary velocity: a partial first arc

Assume $c > 0$. If $v_0 > 0$, the first branch has center $-a_f$, radius

$$R = \sqrt{(x_0 + a_f)^2 + (v_0/\omega)^2},$$

phase $\theta_0 = \text{atan2}(-v_0/\omega, x_0 + a_f)$, first-turn time $\tau_0 = -\theta_0/\omega$, and next turn $X_1 = -a_f + R$. If $|X_1| > a_f$, the remaining complete half-cycle count is

$$r = \left\lceil \frac{|X_1| - a_f}{2a_f} \right\rceil, \quad \tau_{\text{stop}} = \tau_0 + r\pi/\omega. \quad (6)$$

If $|X_1| \leq a_f$, the first arc itself stops in the static interval.

For $v_0 < 0$, replace the center by $+a_f$, use

$$R = \sqrt{(x_0 - a_f)^2 + (v_0/\omega)^2}, \quad \theta_0 = \text{atan2}(-v_0/\omega, x_0 - a_f),$$

with first-turn time $(\pi - \theta_0)/\omega$ and next turn $X_1 = a_f - R$. The same ceiling rule applies. The first segment here is a partial slip arc, not a complete half-cycle; only r is an integer count of later complete half-cycles. At an exterior rest, the positive side has center $+a_f$, phase zero, and time π/ω ; the negative side has center $-a_f$, phase π , and the same time.

4 Harmonic face and finite receipt

When $c = 0$,

$$x(t) = x_0 \cos(\omega t) + (v_0/\omega) \sin(\omega t), \quad v(t) = v_0 \cos(\omega t) - \omega x_0 \sin(\omega t),$$

and E is conserved; there is no finite capture. The receipt contains eight rest rows, eight signed-velocity rows, five static-boundary rows, four harmonic rows, and five work-dissipation rows. The independent checker recomputes every row without importing the producer; SymPy checks fifteen identities, replay compares two fresh trees, and the hostile suite rejects 28/28 mutations. The key `moving_arc_count` is used for moving segments so that a partial first arc is not mislabeled as a half-cycle.

5 Route-A boundary and audit supplement

The oscillator has no intrinsic rational-prime carrier, no prime-power clock, no primitive-orbit product, and no target divisor. The strict evaluator tuple is

$$(\text{AO_FAIL}, \text{A1_FAIL}, \text{A2_FAIL}, \text{A3_FAIL}, \text{A4_FORMAL_HINT}),$$

with `ROUTE_A_REJECTED` and `route_b_invocation_allowed=false`. The finite ledger certifies source-local event identities only; it is not an Artin–Mazur zeta and not a Hilbert–Pólya construction. The scope literal is `NO_BAD_EULER_OR_ROOT_NUMBER`.
